MESON 2021

16th International Workshop on Meson Physics 17th - 20th May 2021

Introduction | Motivation

In this talk we will be concerned with central exclusive production (CEP) of axial-vector $f_1(1285)$ meson in proton-(anti)proton collisions at c.m. energies:

- low: HADES (*pp*) and PANDA ($p\overline{p}$) at FAIR \leftarrow Lebiedowicz, Nachtmann, Salabura, Szczurek, arXiv:2105.07192
- intermediate: WA102, COMPASS
- high: RHIC, LHC ← Lebiedowicz, Leutgeb, Nachtmann, Rebhan, Szczurek, PRD 102 (2020) 114003

The $f_1(1285)$ meson was measured

- in two-photon interactions in e⁺e⁻ reactions (MARKII, TPC/Two-Gamma, L3) see: A. Szczurek, PRD 102 (2020) 113015 ← on production of f₁ mesons at e⁺e⁻ collisions with double-tagging as a way to constrain the axial meson light-by-light contribution to the muon g-2 and hyperfine splitting of muonic hydrogen
- in the photoproduction process $\gamma p \rightarrow f_1 p$ (CLAS Collaboration)
- in proton-proton collisions for c.m. energies 12.7 and 29.1 GeV (WA102) and for 13 TeV at the LHC (ATLAS) [R. Sikora, CERN-THESIS-2020-235]

Why study the $pp \rightarrow ppf_1$ process?

- What is underlying production mechanism for studies of f_1 CEP at near threshold and at LHC?
 - Poorly known VVf₁ and IPIPf₁ coupling strengths and the corresponding vertex form factors
 - Can it be described in holographic QCD?
- What is underlying decay mechanism?
 - e.g., $f_1(1285) \rightarrow 4\pi$ decay via $\rho\rho$ or/and $\pi a_1(1260)(\rightarrow \rho\pi)$
 - transition form factors e.g., $\gamma^* \gamma^* \rightarrow f_1$, $f_1 \rightarrow \gamma \gamma^* \rightarrow \gamma e^+ e^-$
 - What is the nature of the f₁(1285)? For instance, is it a normal qq state or KK* molecule? see: Aceti, Dias, Oset, EPJA 51 (2015) 48; Aceti, Xie, Oset, PLB 750 (2015) 609
- What is optimal observation channel of the $f_1(1285)$?

VV-fusion mechanism

 $p(p_a, \lambda_a) + p(p_b, \lambda_b) \rightarrow p(p_1, \lambda_1) + f_1(k, \lambda_{f_1}) + p(p_2, \lambda_2)$ $p_{a,b}, p_{1,2}$ and $\lambda_{a,b}, \lambda_{1,2} = \pm \frac{1}{2}$: the four-momenta and helicities of protons k and $\lambda_{f_1} = 0, \pm 1$: the four-momentum and helicity of the f_1 meson $q_{1} = p_{a} - p_{1}, \quad q_{2} = p_{b} - p_{2}, \quad k = q_{1} + q_{2}$ $q_{1} = p_{a} - p_{1}, \quad q_{2} = p_{b} - p_{2}, \quad k = q_{1} + q_{2}$ $t_{1} = q_{1}^{2}, \quad t_{2} = q_{2}^{2}, \quad m_{f_{1}}^{2} = k^{2}$ $s = (p_{a} + p_{b})^{2} = (p_{1} + p_{2} + k)^{2}, \text{ c.m. energy squared}$ $s_{1} = (p_{1} + k)^{2}, \quad s_{2} = (p_{2} + k)^{2}$ $p(p_b)$ *VV*-fusion amplitude: $\mathcal{M}_{pp \to ppf_1}^{(VV \text{ fusion})} = \mathcal{M}_{pp \to ppf_1}^{(\rho \rho \text{ fusion})} + \mathcal{M}_{pp \to ppf_1}^{(\omega \omega \text{ fusion})}$ $\mathcal{M}_{\lambda_a \lambda_b \to \lambda_1 \lambda_2 \lambda_{f_a}}^{(VV \text{ fusion})} = (-i) \left(\epsilon^{\alpha} (\lambda_{f_1}) \right)^* \bar{u}(p_1, \lambda_1) i \Gamma_{\mu_1}^{(Vpp)}(p_1, p_a) u(p_a, \lambda_a)$ $\times i\tilde{\Delta}^{(V)\,\mu_1
u_1}(s_1,t_1)\,i\Gamma^{(VVf_1)}_{\nu_1\nu_2\alpha}(q_1,q_2)\,i\tilde{\Delta}^{(V)\,\nu_2\mu_2}(s_2,t_2)$ $\times \bar{u}(p_2,\lambda_2)i\Gamma^{(Vpp)}_{\mu_2}(p_2,p_b)u(p_b,\lambda_b)$ $i\Gamma_{\mu}^{(Vpp)}(p',p) = -i\Gamma_{\mu}^{(V\bar{p}\bar{p})}(p',p) = -ig_{Vpp} F_{VNN}(t) \left[\gamma_{\mu} - i\frac{\kappa_{V}}{2m_{\pi}}\sigma_{\mu\nu}(p-p')^{\nu}\right]$ $g_{opp} = 3.0$, $\kappa_o = 6.1$, $g_{\omega pp} = 9.0$, $\kappa_\omega = 0$ κ_V : tensor-to-vector coupling ratio, $\kappa_V = f_{VNN}/g_{VNN}$ $F_{VNN}(t) = \frac{\Lambda_{VNN}^2 - m_V^2}{\Lambda_{VNN}^2 - t}$

For the proton-antiproton collisions we have

$$\begin{split} \bar{u}(p_2,\lambda_2)i\Gamma^{(Vpp)}_{\mu_2}(p_2,p_b)u(p_b,\lambda_b) &\to \bar{v}(p_b,\lambda_b)i\Gamma^{(V\bar{p}\bar{p})}_{\mu_2}(p_2,p_b)v(p_2,\lambda_2) \\ &= -\bar{u}(p_2,\lambda_2)i\Gamma^{(Vpp)}_{\mu_2}(p_2,p_b)u(p_b,\lambda_b) \\ \mathcal{M}^{(VV\,\text{fusion})}_{p\bar{p}\to p\bar{p}M} &= -\mathcal{M}^{(VV\,\text{fusion})}_{pp\to ppM} \end{split}$$

The standard form of the vector-meson propagator:

$$\begin{split} i\Delta_{\mu\nu}^{(V)}(k) &= i\left(-g_{\mu\nu} + \frac{k_{\mu}k_{\nu}}{k^2 + i\epsilon}\right)\Delta_T^{(V)}(k^2) - i\frac{k_{\mu}k_{\nu}}{k^2 + i\epsilon}\Delta_L^{(V)}(k^2) \\ \Delta_T^{(V)}(t) &= (t - m_V^2)^{-1} \end{split}$$

For higher values of s_1 and s_2 we must take into account reggeization:

$$\Delta_T^{(V)}(t_i) \to \tilde{\Delta}_T^{(V)}(s_i, t_i) = \Delta_T^{(V)}(t_i) \left(\exp(i\phi(s_i)) \frac{s_i}{s_{\text{thr}}} \right)^{\alpha_V(t_i) - 1}$$
$$\phi(s_i) = \frac{\pi}{2} \exp\left(\frac{s_{\text{thr}} - s_i}{s_{\text{thr}}}\right) - \frac{\pi}{2}$$

where s_{thr} is the lowest value of s_i possible here: $s_{\text{thr}} = (m_p + m_{f_1})^2$ We use the linear form for the vector meson Regge trajectories :

 $\alpha_V(t) = \alpha_V(0) + \alpha'_V t$, $\alpha_V(0) = 0.5$, $\alpha'_V = 0.9 \text{ GeV}^{-2}$

$$\begin{aligned} VVf_{1} \text{ coupling} \\ \mathcal{L}'_{VVf_{1}}(x) &= \frac{1}{M_{0}^{4}}g_{VVf_{1}}\left(V_{\kappa\lambda}(x)\stackrel{\leftrightarrow}{\partial_{\mu}}\stackrel{\leftrightarrow}{\partial_{\nu}}V_{\rho\sigma}(x)\right)\left(\partial_{\alpha}U_{\beta}(x) - \partial_{\beta}U_{\alpha}(x)\right)g^{\kappa\rho}g^{\mu\sigma}\varepsilon^{\lambda\nu\alpha\beta} \\ \text{where } V_{\kappa\lambda}(x) &= \partial_{\kappa}V_{\lambda}(x) - \partial_{\lambda}V_{\kappa}(x), \ U_{\alpha}(x) \text{ and } V_{\kappa}(x) \text{ are the fields of the } f_{1} \\ \text{meson and the vector meson } V, \text{ respectively.} \\ M_{0} &\equiv 1 \text{ GeV and } g_{VVf_{1}} \text{ a dimensionless coupling constant.} \\ i\Gamma_{\mu\nu\alpha}^{(VVf_{1})}(q_{1},q_{2}) &= \frac{2g_{VVf_{1}}}{M_{0}^{4}}\left[(q_{1}-q_{2})^{\rho}(q_{1}-q_{2})^{\sigma}\varepsilon_{\lambda\sigma\alpha\beta}k^{\beta} \\ &\quad \times (q_{1\kappa}\delta^{\lambda}_{\ \mu}-q_{1}^{\lambda}g_{\kappa\mu})(q_{2}^{\kappa}g_{\rho\nu}-q_{2\rho}\delta^{\kappa}_{\nu}) + (q_{1}\leftrightarrow q_{2},\mu\leftrightarrow\nu)\right] \\ &\quad \times F^{(VVf_{1})}(q_{1}^{2},q_{2}^{2},k^{2}) \\ \text{satisfies gauge invariance relations: } \Gamma_{\mu\nu\alpha}^{(VVf_{1})}(q_{1},q_{2})q_{1}^{\mu} = 0, \Gamma_{\mu\nu\alpha}^{(VVf_{1})}(q_{1},q_{2})q_{2}^{\nu} = 0 \\ F^{(VVf_{1})}(q_{1}^{2},q_{2}^{2},m_{f_{1}}^{2}) = \tilde{F}_{V}(q_{1}^{2})\tilde{F}_{V}(q_{2}^{2})F(m_{f_{1}}^{2}) = \frac{\Lambda_{V}^{4}}{\Lambda^{4} + (t_{2}-m^{2})^{2}}\frac{\Lambda_{V}^{4}}{\Lambda^{4} + (t_{2}-m^{2})^{2}} \end{aligned}$$

with
$$F(m_{f_1}^2) = 1$$

Results

R. Dickson et al. (CLAS Collaboration), PRC 93 (2016) 065202

The $\rho\rho f_1$ coupling constant is extracted from the radiative decay rate $f_1 \rightarrow \rho^0 \gamma$ using the VMD approach.

from PDG : $\Gamma(f_1(1285) \to \gamma \rho^0) = 1384.7^{+305.1}_{-283.1} \text{ keV}$

from CLAS : $\Gamma(f_1(1285) \rightarrow \gamma \rho^0) = (453 \pm 177) \text{ keV}$ we use We consider decay $f_1 \rightarrow \rho^0 \gamma \rightarrow \pi^+ \pi \gamma$ taking ρ^0 mass distribution. We estimate the cotoff parameter Λ_ρ in the $f_1 \rho \rho$ form factor:

 $F_{\rho\rho f_1}(k_{\rho}^2, k_{\gamma}^2, k^2) = F_{\rho\rho f_1}(k_{\rho}^2, 0, m_{f_1}^2) = \tilde{F}_{\rho}(k_{\rho}^2)\tilde{F}_{\rho}(0)F(m_{f_1}^2) = \tilde{F}_{\rho}(k_{\rho}^2)\tilde{F}_{\rho}(0)$

Photoproduction process:

We assume $g_{\omega\omega f_1} = g_{\rho\rho f_1}$ based on arguments from the quark model and VMD. We assume $\Lambda_{\rho} = \Lambda_{\omega} = \Lambda_{V}$ and $\Lambda_{\rho NN} = \Lambda_{\omega NN} = \Lambda_{VNN}$. Reggeization effect included

The t-channel V-exchange mechanism play a crucial role in reproducing the forward-peaked angular distributions, especially at higher energies. From the comparison of differential cross sections to the CLAS data we estimate:

 $\begin{array}{l} ({\rm C7}): \Lambda_{VNN} = 1.35 \; {\rm GeV} \; {\rm for} \; \Lambda_{V} = 0.65 \; {\rm GeV} \; , |g_{VVf_{1}}| = 20.03 \\ ({\rm C9}): \Lambda_{VNN} = 1.01 \; {\rm GeV} \; {\rm for} \; \Lambda_{V} = 0.8 \; {\rm GeV} \; , |g_{VVf_{1}}| = 12.0 \\ ({\rm C10}): \Lambda_{VNN} = 0.9 \; {\rm GeV} \; {\rm for} \; \Lambda_{V} = 1.0 \; {\rm GeV} \; , |g_{VVf_{1}}| = 8.49 \\ ({\rm C11}): \Lambda_{VNN} = 0.834 \; {\rm GeV} \; {\rm for} \; \Lambda_{V} = 1.5 \; {\rm GeV} \; , |g_{VVf_{1}}| = 6.59 \end{array}$

(C11) is excluded due to small $\Lambda_{\text{VNN}},$ we stay with (C7) – (C10)

Missing N* resonances and s/u-channel proton exchange Possible N(2300) contribution

 \rightarrow postulated in Y.-Y. Wang et al., PRD 95 (2017) 096015

Results

 Diffractive contribution (IPIP fusion) is very small for the HADES and PANDA energy range

 → IPIP-fusion contribution should be considered as upper limit of the cross section.
 If at the WA102 c.m. energy (29.1 GeV) there are important contributions from subleading reggeon exchanges, the IPIP contribution could be smaller (by a factor of up to 4)

Results

 \sqrt{s} = 3.46 GeV (top) and 5.0 GeV (bottom)

- At near threshold energy (HADES) the values of small $|t_1|$ and $|t_2|$ are not accessible kinematically
- HADES and PANDA experiments have a good opportunity to study physics of large four-momentum transfer squared \rightarrow probes corresponding form factors at relatively large values of $|t_{1,2}|$
- $\rho^{0}\rho^{0}$ and $\omega\omega$ -fusion processes have different kinematic dependences. Both terms play similar role. But with increasing c.m. energy the averages of $|t_{1,2}|$ decrease

(damping by form factors), hence the $\omega\omega$ term becomes more important

 We predict a strong preference for the outgoing nucleons to be produced with their transverse momenta being back-to-back,

 $d\sigma/d\phi_{pp} \text{ at } \phi_{pp} = \pi$ $\phi_{pp} \qquad (0 \leqslant \phi_{pp} \leqslant \pi)$ $\phi_{p2\perp} \qquad 6$

Results

Optimal observation channel of $f_{1}(1285)$

Pomeron-Pomeron fusion mechanism

At high energies double pomeron (IP) exchange is dominant production mechanism of the $f_1(1285)$ see: Lebiedowicz, Leutgeb, Nachtmann, Rebhan, Szczurek, PRD 102 (2020) 114003 $p\left(\boldsymbol{p}_{a}\right)+p\left(\boldsymbol{p}_{b}\right)\rightarrow p\left(\boldsymbol{p}_{1}\right)+\boldsymbol{f}_{1}\left(\boldsymbol{k}\right)+p\left(\boldsymbol{p}_{2}\right)$

We treat our reaction in the <u>tensor-pomeron approach</u> [Ewerz, Maniatis, Nachtmann, Ann. Phys. 342 (2014) 31]

The pomeron and the charge conjugation C=+1 reggeons are described as effective rank 2 symmetric tensor exchanges. The odderon and the C=-1 reggeons are described as effective vector exchanges.

This approach has a good basis from nonperturbative QCD considerations. The IP exchange can be understood as a coherent sum of exchanges of spin 2+4+6+ ... [Nachtmann, Ann. Phys. 209 (1991) 436]

A tensor character of the pomeron is also preferred in holographic QCD, see e.g., Brower, Polchinski, Strassler, Tan, JHEP 12 (2007) 005 Domokos, Harvey, Mann, PRD 80 (2009) 126015 Iatrakis, Ramamurti, Shuryak, PRD 94 (2016) 045005 The Born-level amplitude within the tensor-pomeron approach:

The Born-level amplitude within the tensor-pomeron approach:

$$\mathcal{M}_{\lambda_{a}\lambda_{b}\to\lambda_{1}\lambda_{2}\lambda_{f_{1}}}^{\text{Born}} = (-i) \left(\epsilon^{\mu}(\lambda_{f_{1}})\right)^{*} \bar{u}(p_{1},\lambda_{1}) i \Gamma_{\mu_{1}\nu_{1}}^{(I\!\!P\,pp)}(p_{1},p_{a}) u(p_{a},\lambda_{a}) \\
\times i \Delta^{(I\!\!P)\,\mu_{1}\nu_{1},\alpha_{1}\beta_{1}}(s_{1},t_{1}) i \Gamma_{\alpha_{1}\beta_{1},\alpha_{2}\beta_{2},\mu}^{(I\!\!P\,I\!P\,f_{1})}(q_{1},q_{2}) i \Delta^{(I\!\!P)\,\alpha_{2}\beta_{2},\mu_{2}\nu_{2}}(s_{2},t_{2}) \\
\times \bar{u}(p_{2},\lambda_{2}) i \Gamma_{\mu_{2}\nu_{2}}^{(I\!\!P\,pp)}(p_{2},p_{b}) u(p_{b},\lambda_{b})$$
with terms of the effective pomeron propagator and the pomeron-proton vertex

with terms of the effective pomeron propagator and the pomeron-proton vertex

$$\begin{split} i\Delta_{\mu\nu,\kappa\lambda}^{(I\!\!P)}(s,t) &= \frac{1}{4s} \left(g_{\mu\kappa}g_{\nu\lambda} + g_{\mu\lambda}g_{\nu\kappa} - \frac{1}{2}g_{\mu\nu}g_{\kappa\lambda} \right) (-is\alpha'_{I\!\!P})^{\alpha_{I\!\!P}(t)-1} \\ i\Gamma_{\mu\nu}^{(I\!\!P\,pp)}(p',p) &= -i3\beta_{I\!\!PNN}F_1 \big((p'-p)^2 \big) \left\{ \frac{1}{2} [\gamma_{\mu}(p'+p)_{\nu} + \gamma_{\nu}(p'+p)_{\mu}] - \frac{1}{4}g_{\mu\nu}(p'+p) \right\} \\ &\alpha_{I\!\!P}(t) = \alpha_{I\!\!P}(0) + \alpha'_{I\!\!P}t \,, \quad \alpha_{I\!\!P}(0) = 1.0808, \quad \alpha'_{I\!\!P} = 0.25 \,\mathrm{GeV}^{-2} \\ &\beta_{I\!\!PNN} = 1.87 \,\mathrm{GeV}^{-1}, \quad F_1(t): \text{ Dirac form factor of the proton} \\ &\mathrm{Ewerz, Maniatis, Nachtmann, Ann, Phys. 342 (2014) 31} \end{split}$$

Absorption effects:

$$\mathcal{M}_{pp \to ppf_1} = \mathcal{M}_{pp \to ppf_1}^{\mathrm{Born}} + \mathcal{M}_{pp \to ppf_1}^{pp-\mathrm{rescattering}}$$
$$\mathcal{M}_{pp \to ppf_1}^{pp-\mathrm{rescattering}}(s, \vec{p}_{1\perp}, \vec{p}_{2\perp}) = \frac{i}{8\pi^2 s} \int d^2 \vec{k}_{\perp} \mathcal{M}_{pp \to ppf_1}^{\mathrm{Born}}(s, \vec{p}_{1\perp} - \vec{k}_{\perp}, \vec{p}_{2\perp} + \vec{k}_{\perp}) \mathcal{M}_{pp \to pp}^{IP-\mathrm{exchange}}(s, -\vec{k}_{\perp}^2)$$
where \vec{k}_{\perp} is the transverse momentum carried around the loop

IP IP f1 coupling

 $\begin{array}{c} & \mathbb{P}_{\kappa\lambda} \\ q_1 \\ q_2 \\ q_2 \\ \mathbb{P}_{\rho\sigma} \end{array} \xrightarrow{k} f_{1\alpha}$

coupling Lagrangian $\mathcal{L}^{(I\!\!P I\!\!P f_1)}$ "bare" vertex function $i\Gamma^{(I\!\!P I\!\!P f_1)}_{\kappa\lambda,\rho\sigma,\alpha}(q_1,q_2)|_{\text{bare}}$ \downarrow CEP reaction

vertex function supplemented by suitable form factor $i\Gamma^{(I\!\!P I\!\!P f_1)}_{\kappa\lambda,\rho\sigma,\alpha}(q_1,q_2) = i\Gamma^{(I\!\!P I\!\!P f_1)}_{\kappa\lambda,\rho\sigma,\alpha}(q_1,q_2) \mid_{\text{bare}} \tilde{F}_{I\!\!P I\!\!P f_1}(q_1^2,q_2^2,k^2)$

For the on-shell meson we have set $k^2 = m_{f_1}^2$. $\tilde{F}^{(I\!\!P I\!\!P f_1)}(t_1, t_2, m_{f_1}^2) = F_M(t_1)F_M(t_2), \quad F_M(t) = \frac{1}{1 - t/\Lambda_0^2}, \quad \Lambda_0^2 = 0.5 \text{ GeV}^2$ or

$$\tilde{F}^{(I\!\!P I\!\!P f_1)}(t_1, t_2, m_{f_1}^2) = \exp\left(\frac{t_1 + t_2}{\Lambda_E^2}\right)$$

where the cutoff constant Λ_E should be adjusted to experimental data

We follow two strategies for constructing coupling Lagrangian:

(1) Phenomenological approach. First we consider a fictitious process: the fusion of two "real spin 2 pomerons" (or tensor glueballs) of mass m giving an f_1 meson of $J^{PC} = 1^{++}$

$$I\!\!P(m,\epsilon_1) + I\!\!P(m,\epsilon_2) \to f_1(m_{f_1},\epsilon)$$

 $\epsilon_{1,2}$: polarisation tensors, ϵ : polarisation vector

$$I\!\!P \xrightarrow{\vec{q}} f_1 \xrightarrow{-\vec{q}} I\!\!P$$

We work in the rest system of the f_1 meson:

The spin 2 of these "real pomerons" can be combined to a total spin S ($0 \le S \le 4$) and this must be combined with the orbital angular momentum ℓ to give $J^{PC} = 1^{++}$ of the f_1 state. There are exactly two possibilities: (ℓ ,S) = (2,2) and (4,4).

Corresponding couplings are:

$$\mathcal{L}_{I\!\!PI\!Pf_1}^{(2,2)} = \frac{g'_{I\!\!PI\!Pf_1}}{32\,M_0^2} \Big(I\!\!P_{\kappa\lambda} \stackrel{\leftrightarrow}{\partial}_{\mu} \stackrel{\leftrightarrow}{\partial}_{\nu} I\!\!P_{\rho\sigma} \Big) \Big(\partial_{\alpha} U_{\beta} - \partial_{\beta} U_{\alpha} \Big) \Gamma^{(8)\,\kappa\lambda,\rho\sigma,\mu\nu,\alpha\beta} \\ \mathcal{L}_{I\!\!PI\!Pf_1}^{(4,4)} = \frac{g''_{I\!\!PI\!Pf_1}}{24 \times 32\,M_0^4} \Big(I\!\!P_{\kappa\lambda} \stackrel{\leftrightarrow}{\partial}_{\mu_1} \stackrel{\leftrightarrow}{\partial}_{\mu_2} \stackrel{\leftrightarrow}{\partial}_{\mu_3} \stackrel{\leftrightarrow}{\partial}_{\mu_4} I\!\!P_{\rho\sigma} \Big) \Big(\partial_{\alpha} U_{\beta} - \partial_{\beta} U_{\alpha} \Big) \Gamma^{(10)\,\kappa\lambda,\rho\sigma,\mu_1\mu_2\mu_3\mu_4,\alpha\beta}$$

Here $M_0 \equiv 1$ GeV, $g'_{I\!\!P I\!\!P f_1}, g''_{I\!\!P I\!\!P f_1}$: dimensionless coupling parameters, $I\!\!P_{\kappa\lambda}$ effective pomeron field, $U_{\alpha} f_1$ field, $\overleftrightarrow{\partial}_{\mu} = \overrightarrow{\partial}_{\mu} - \overleftarrow{\partial}_{\mu}$ asymmetric derivative, and $\Gamma^{(8)}, \Gamma^{(10)}$ are known tensor functions. (2) Holographic QCD approach using the <u>Sakai-Sugimoto model</u>. There, the *IP IP f₁* coupling can be derived from the bulk <u>Chern-Simons (CS) term</u> requiring consistency of supergravity and the gravitational anomaly.

$$\mathcal{L}^{\mathrm{CS}} = \varkappa' U_{\alpha} \, \varepsilon^{\alpha\beta\gamma\delta} \, I\!\!P^{\mu}_{\ \beta} \, \partial_{\delta} I\!\!P_{\gamma\mu} + \varkappa'' U_{\alpha} \varepsilon^{\alpha\beta\gamma\delta} \left(\partial_{\nu} P^{\mu}_{\ \beta} \right) \left(\partial_{\delta} \partial_{\mu} I\!\!P^{\nu}_{\ \gamma} - \partial_{\delta} \partial^{\nu} I\!\!P_{\gamma\mu} \right)$$

$$\varkappa' : \text{dimensionless}, \quad \varkappa'' : \text{dimension GeV}^{-2}$$

Sakai, Sugimoto, Prog. Theor. Phys. 113 (2005) 843; 114 (2005) 1083, Leutgeb, Rebhan, PRD 101 (2020) 114015

For our fictitious reaction with real pomerons there is strict equivalence $\mathcal{L}^{CS} \cong \mathcal{L}^{(2,2)} + \mathcal{L}^{(4,4)}$ if the couplings satisfy: $g'_{I\!\!PI\!\!Pf_1} = -\varkappa' \frac{M_0^2}{k^2} - \varkappa'' \frac{M_0^2(k^2 - 2m^2)}{2k^2}$ $g''_{I\!\!PI\!\!Pf_1} = \chi'' \frac{2M_0^4}{k^2}$

where k^2 is invariant mass squared of the resonance f_1 .

For the CEP reaction

the pomerons have invariant mass squared t_1 , $t_2 < 0$ instead of m^2 and, in general, $t_2 \neq t_2$. Replacing above $2m^2 \rightarrow t_1 + t_2$ we expect for small $|t_1|$ and $|t_2|$ still approximate equivalence to hold. This is confirmed by explicit numerical studies.

Comparison with experimental results from WA102@CERN

Comparison with experimental results from WA102@CERN

Comparison with data from: A. Kirk (WA102 Collaboration), Nucl. Phys. A 663 (2000) 608 The theoretical results have been normalized to the mean value of the number of events

- An almost 'flat' distribution at large values of $|t_1 t_2|$ can be observed
 - → absorption effects play a significant role there, large damping of cross section at higher values of ϕ_{oo}
- It seems that the (l,S) = (4,4) term best reproduces the shape of the WA102 data

Holographic QCD approach

← Fit to WA102 data using the Chern-Simons (CS) coupling.

The relation between the (ℓ ,S) and CS forms of the couplings: With $\varkappa' = -8.88$, $\varkappa''/\varkappa' = -1.0 \text{ GeV}^{-2}$

and setting $t_1 = t_2 = -0.1 \text{ GeV}^2$

we get: $g'_{I\!\!P I\!\!P f_1} = 0.42$, $g''_{I\!\!P I\!\!P f_1} = 10.81$ This CS coupling corresponds practically to a pure $(\ell, S) = (4, 4)$ coupling!

<u>The prediction for \varkappa''/\varkappa' obtained in the Sakai-Sugimoto model</u>: $\varkappa''/\varkappa' = -5.631/M_{KK}^2 = -(6.25, 3.76, 2.44) \text{ GeV}^{-2}$ for $M_{KK} = (949, 1224, 1519) \text{ MeV}$

Usually $M_{\kappa\kappa}$ (Kaluza-Klein mass scale) is fixed by matching the mass of the lowest vector meson to that of the physical ρ meson, leading to $M_{\kappa\kappa}$ = 949 MeV. However, this choice leads to tensor glueball mass which is too low, $M_{\tau} \approx 1.5$ GeV. The standard pomeron trajectory corresponds to $M_{\tau} \approx 1.9$ GeV, whereas lattice gauge theory indicates $M_{\tau} \approx 2.4$ GeV.

Predictions for the LHC experiments

Cross sections in μb for $pp \rightarrow ppf_1(1285)$ for $\sqrt{s} = 13$ TeV:

Contribution	Parameters	$ y_{f_1} < 1.0$	$ y_{f_1} < 2.5$	$ y_{f_1} < 2.5,$	$2.0 < y_{f_1} < 4.5$
	$\Lambda_E = 0.7 \mathrm{GeV},$			$0.17 < p_{y,p} < 0.50 \text{ GeV}$	
(l,S) = (2,2)	$g'_{I\!\!P I\!\!P f_1} = 4.89$	14.8	37.5	6.46	18.9
(l,S) = (4,4)	$g''_{I\!\!P I\!\!P f_1} = 10.31$	13.8	34.0	6.06	18.1
(\varkappa',\varkappa'')	$\varkappa''/\varkappa' = -6.25 \text{ GeV}^{-2}$	18.6	45.8	7.14	23.1
(\varkappa',\varkappa'')	$\varkappa''/\varkappa' = -2.44 \text{ GeV}^{-2}$	17.5	43.4	7.10	22.1
(\varkappa',\varkappa'')	$\varkappa''/\varkappa' = -1.0 \text{ GeV}^{-2}$	16.6	41.0	7.09	20.5

Predictions for the LHC experiments

- One of the most prominent decay modes of the $f_1(1285)$ is $f_1(1285) o \pi^+\pi^-\pi^+\pi^-$
- There $f_1(1285)$ and $f_2(1270)$ are close in mass. We obtain for $\sqrt{s} = 13$ TeV and $|y_M| < 2.5$:

$$\begin{split} \sigma_{pp \to ppf_1(1285)} \times \mathcal{BR}(f_1(1285) \to 2\pi^+ 2\pi^-) &= 34.0 \ \mu b \times 0.112 = 3.8 \ \mu b \\ \sigma_{pp \to ppf_2(1270)} \times \mathcal{BR}(f_2(1270) \to 2\pi^+ 2\pi^-) = 11.3 \ \mu b \times 0.028 = 0.3 \ \mu b \\ &\leftarrow \text{CEP of } f_2(1270): \text{Lebiedowicz et al.}, \\ \text{PRD 93 (2016) 054015, PRD 101 (2020) 034008} \end{split}$$

As the $f_1(1285)$ has a much narrower width than the $f_2(1270)$ it would be seen in the M(4 π) distribution as a peak on top of broader $f_2(1270)$ and of the continuum background

- f_1 (1285) is seen in the preliminary ATLAS-ALFA results for $pp \rightarrow pp\pi^+\pi^-\pi^+\pi^-$ at $\sqrt{s} = 13$ TeV and for $|\eta_{\pi}| < 2.5, p_{t,\pi} > 0.1 \text{ GeV}, \max(p_{t,\pi}) > 0.2 \text{ GeV}, 0.17 \text{ GeV} < |p_{y,p}| < 0.5 \text{ GeV}$ [R. Sikora, CERN-THESIS-2020-235]
- Theoretical studies of the reaction $pp \rightarrow pp 4\pi$ including both the resonances and continuum contributions within the tensor-pomeron approach \rightarrow in progress:

Conclusions

- We have given predictions for forthcoming experiments with HADES and PANDA at FAIR. We have performed feasibility studies and estimated that a 30-days measurement with HADES should allow to identify f₁(1285) meson in the π⁺π⁻η channel. From such experiments we will learn more on the production mechanism, in particular, about the ρρf₁ and ωωf₁ coupling strengths.
- We have discussed in detail CEP of f₁(1285) meson in pp collisions at high energies in the tensor-pomeron approach. Different forms of the IP IP f₁ coupling are possible. Tests of the Sakai-Sugimoto model are possible.
- We obtain a good description of the WA102 data for the $pp \rightarrow pp f_1(1285)$ reaction assuming that the reaction is dominated by IP exchange. We have given predictions for experiments at the LHC. We have included - very important - absorptive corrections.

Experimental studies of single meson CEP reactions will give many *IP IP M* coupling parameters. Their theoretical calculation is a challenging problem of nonperturbative QCD.

Results (HADES and PANDA)

 $p(p_1) = p(p_a)$

 $- \rho^0(p_2)$

Other decay channels?

 $p(p_a)$

PDG: $\mathcal{BR}(f_1(1285) \to \rho^0 \gamma) = (6.1 \pm 1.0) \%$

CLAS: $\mathcal{BR}(f_1(1285) \to \rho^0 \gamma) = (2.5^{+0.7}_{-0.8}) \%$

• For the 4π channel it may be difficult to identify the $f_1(1285)$ due to large continuum background e.g. pp $\rightarrow N(1440)N(1440) \rightarrow N\pi\pi N\pi\pi$ \rightarrow we have found that fusion mechanisms for the $\rho^0\rho^0$ production: $\pi^0-\omega-\pi^0$ and $\omega-\pi^0-\omega$ exchanges (treated with exact $2 \rightarrow 4$ kinematics) give much smaller background cross sections

The $\rho^0 \gamma$ channel should be much better suited. There, however, dominant background channel $pp\pi^+\pi^-\pi^0$ is of the order of 2 mb [1] and ρ^0 is so broad that it will not provide sufficient reductions (as it is the case in η decay channel)

 $\Lambda \Lambda \gamma (p_4)$ $\wedge \wedge \gamma (p_4)$ $- (p_4)$ $+ (\mathbf{p}_a \leftrightarrow p_b, p_1 \leftrightarrow p_2)$ $p(p_b)$ $p(p_b)$ $p(p_2)$ $\overline{p}(p_b)$ $p(p_2)$ 10 $d\sigma/dM_{\rho^{0\gamma}}$ (nb/GeV) (nb/GeV) $pp \rightarrow pp \rho^0 \gamma$ $p\overline{p} \rightarrow p\overline{p} \rho^0 \gamma$ $\sqrt{s} = 3.46 \text{ GeV}$ $\sqrt{s} = 5.0 \text{ GeV}$ $10^{3} = \Lambda_{V} = 0.65 \text{ GeV}$ $\Lambda_{VNN} = 1.35 \text{ GeV}$ 10^{2} $f_{1}(1285)$ $- f_1(1285)$ continuum, total continuum, total $d\sigma/dM_{\rho^{0}\gamma}$ (= 20.03continuum, $\pi\pi$ continuum, $\pi\pi$ continuum, VV $\Lambda_{\rm V} = 0.65 \text{ GeV} =$ $\Lambda_{\rm VNN} = 1.35 \text{ GeV}$ continuum, VV 10^{2} 10 $|g_{VVf}| = 20.03$ 10 10^{-1} 10^{-2} 10^{-} 0.8 1.2 1.4 1.8 1.2 1.4 1.6 0.8 1.6 1 1.8 $M_{0^{0}\gamma}$ (GeV) $M_{0^{0}\gamma}$ (GeV)

 $p(p_1) = p(p_a)$

 $p(p_1)$

The π -continuum contribution is larger than the VV-continuum term. In both cases the f₁ resonance is clearly visible, even without the reggeization (green lines) in the continuum processes. We get: for $\sqrt{s} = 3.46 \text{ GeV}$: $\sigma_{pp \to pp(f_1 \to \rho^0 \gamma)} = 5.38 \text{ nb}$

for $\sqrt{s} = 5.0 \text{ GeV}$: $\sigma_{p\bar{p} \to p\bar{p}(f_1 \to \rho^0 \gamma)} = 62.86 \text{ nb} \leftarrow 10 \text{ x larger}$ This result makes us rather optimistic that an experimental study of the f_1 in the $\rho\gamma$ decay channel should be possible at PANDA@FAIR.

For our exploratory study we have neglected interference effects between the background $\rho\gamma$ and the signal $f_1 \rightarrow \rho\gamma$ processes. We have also neglected the background processes due to bremsstrahlung of γ and ρ^o from the nucleon lines.
